Background and Rational

- Cytoreductive nephrectomy (CN) prior to systemic therapy has been the standard of care for synchronous metastatic renal cell carcinoma (mRCC) patients.
- The introduction of effective tyrosine kinase therapy for mRCC has raised the question whether surgery is still useful in the front line setting of synchronous mRCC.
- The CARMENA (Cancer du Rein Metastatique Nephrectomie et Antiangiogeniques) trial investigated the use of CN in combination with TKI therapy versus TKI therapy alone.
- Conducted over eight years, enrolling 450 patients across Europe, CARMENA demonstrated in an intention to treat analysis that systemic therapy using sunitinib alone is not worse than CN plus sunitinib in mRCC (hazard ratio HR: 0.89, 95% confidence interval (CI), 0.71-1.10)\(^1\).
- Following the publication of these results, KCCure sought to assess patient views related to the surgical approach using CN.

Methods

- The patient survey was designed by KCCure, a U.S. based non-profit patient advocacy organization, specializing in research funding for kidney cancer. In conjunction with members of the European Association of Urology (EAU) Renal Cell Carcinoma Guidelines Panel and the Discussant of the original ASCO presentation
- KCCure conducted a survey among kidney cancer patients via SurveyMonkey immediately following publication of the CARMENA data
- The survey was disseminated in various RCC patient communities using social media and posted to the KCCure website
- The survey had a reach of approximately 1,000 patients with RCC between June 3 and June 9 2018
- N = 185 patients responded

Results

- N=185 patients responded with 60.5% being female.
- Median age was 56.5 years (range 26-84).
- 90% of the responders already had a nephrectomy (NX)
- 38% were stage IV at diagnosis
- 46% were under systemic therapy (Tx)
- On the question of whether they would want CN 75% of all the patients indicated they would still prefer nephrectomy
- 85% of patients on systemic therapy still would want to have a CN
- 79% of the patients who had NX and are on systemic therapy would want to have a CN after CARMENA despite a lack of an OS benefit
- Of the patients with primary metastatic disease and the tumor in place treated with systemic therapy, 20% still wanted a nephrectomy to remove the kidney tumor to be removed despite the CARMENA results
- The results were independent of prior experience of systemic therapy, gender, race and age

Conclusions

- Despite the lack of an OS benefit, the majority of patients want their primary tumor resected
- OS should not be overestimated as the most important aim in this setting
- Patients may think differently about benefits, risks and value of surgical procedures than physicians
- Future guidelines related to CN should take into consideration patient preferences and concerns to ensure that patients aren’t left without hope
- We should reconsider the use of terms such as “poor risk” when defining patient populations who aren’t candidates for CN
- Future investigations related to surgical management of RCC should include patient reported outcomes
